

Between the first and second submissions, we've made two main changes in the design:

- 1) Added the TaskService class in the service layer
- 2) Added the ServiceController class in the service layer

The TaskService class was added to increase the cohesion of the BoardService class, which handled all Task related functions until the new class was implemented. Now, some of the Task's functionality was moved to the TaskService class, making both of the relevant classes highly cohesive.

The ServiceController was added in order to lower the coupling between the service classes. It holds a reference to the other service classes, making it redundant for them to know each other, which lowers the coupling between them.
